Exercise 8: Working with Pandas DataFrames

Download the Pandas practice table "pokemon.csv" from Learning Central (from the "CMT307/Python Bootcamp/Exercises" folder), upload it to your Google Colab (temporary) file area, and load it into Python using the following statements:

```
import pandas as pd

pok = pd.read_csv( "pokemon.csv" )
```

1. Write code which prints out a list of _column names_ in the Pokemon DataFrame.

2. Using the "Type 1" column, create a list of unique names in that column. Iterate over those names, and calculate the proportion of all rows which that "Type 1" represents. Which is the largest type in the DataFrame, and what percentage of all entries does it represent?

3. Set the DataFrame's index to the column "Type 1", and store this in a new variable ("pok_type1" perhaps?). Selecting only the "Grass" type 1s, calculate the sum of both "Attack" and "Speed" columns for each of these Pokemon. Which is the largest total, and what is the name of the Pokemon to which this belongs?

4. Check that your finding is true: use the name string you extracted in (3) to fetch that Pokemon's row from the original DataFrame, and manually check its "Attack" and "Speed" values sum to the correct amount.
